

Package ‘eyeris’

June 19, 2026

Type Package

Title Flexible, Extensible, & Reproducible Pupillometry Preprocessing

Version 3.2.0

Date 2026-06-18

Language en-US

Description Pupillometry offers a non-invasive window into the mind and has been used extensively as a psychophysiological readout of arousal signals linked with cognitive processes like attention, stress, and emotional states [Clewett et al. (2020) <[doi:10.1038/s41467-020-17851-9](https://doi.org/10.1038/s41467-020-17851-9)>; Kret & Sjak-Shie (2018) <[doi:10.3758/s13428-018-1075-y](https://doi.org/10.3758/s13428-018-1075-y)>; Strauch (2024) <[doi:10.1016/j.tins.2024.06.002](https://doi.org/10.1016/j.tins.2024.06.002)>]. Yet, despite decades of pupillometry research, many established packages and workflows to date lack design patterns based on Findability, Accessibility, Interoperability, and Reusability (FAIR) principles [see Wilkinson et al. (2016) <[doi:10.1038/sdata.2016.18](https://doi.org/10.1038/sdata.2016.18)>]. 'eyeris' provides a modular, performant, and extensible preprocessing framework for pupillometry data with BIDS-like organization and interactive output reports [Esteban et al. (2019) <[doi:10.1038/s41592-018-0235-4](https://doi.org/10.1038/s41592-018-0235-4)>; Gorgolewski et al. (2016) <[doi:10.1038/sdata.2016.44](https://doi.org/10.1038/sdata.2016.44)>]. Development was supported, in part, by the Stanford Wu Tsai Human Performance Alliance, Stanford Ric Weiland Graduate Fellowship, Stanford Center for Mind, Brain, Computation and Technology, NIH National Institute on Aging Grants (R01-AG065255, R01-AG079345), NSF GRFP (DGE-2146755), McKnight Brain Research Foundation Clinical Translational Research Scholarship in Cognitive Aging and Age-Related Memory Loss, American Brain Foundation, and the American Academy of Neurology.

bidsify	<i>Save out pupil time series data in a BIDS-like structure</i>
---------	---

Description

This method provides a structured way to save out pupil data in a BIDS-like structure. The method saves out epoched data as well as the raw pupil time series, and formats the directory and filename structures based on the metadata you provide.

Usage

```
bidsify(
    eyeris,
    save_all = TRUE,
    epochs_list = NULL,
    bids_dir = NULL,
    participant_id = NULL,
    session_num = NULL,
    task_name = NULL,
    run_num = NULL,
    save_raw = TRUE,
    html_report = TRUE,
    report_seed = 0,
    report_epoch_grouping_var_col = "matched_event",
    verbose = TRUE,
    csv_enabled = TRUE,
    db_enabled = FALSE,
    db_path = "my-project",
    parallel_processing = FALSE,
    merge_epochs = deprecated(),
    merge_runs = deprecated(),
    pdf_report = deprecated()
)
```

Arguments

eyeris	An object of class eyeris derived from load_asc()
save_all	Logical flag indicating whether all epochs are to be saved or only a subset of them. Defaults to TRUE

epochs_list	List of epochs to be saved. Defaults to NULL
bids_dir	Base bids_directory. Defaults to NULL
participant_id	BIDS subject ID. Defaults to NULL
session_num	BIDS session ID. Defaults to NULL
task_name	BIDS task ID. Defaults to NULL
run_num	BIDS run ID. Optional override for the run number when there's only one block of data present in a given .asc file. This allows you to manually specify a run number (e.g., "03") instead of using the default block number in .asc files (1). This is especially useful if you have a single .asc file for a single run of a task and want your BIDSified derivatives to be labeled correctly. However, for files with multiple recording blocks embedded within the same .asc file, this parameter is ignored and blocks are automatically numbered as runs (block 1 = run-01, block 2 = run-02, etc.) in the order they appeared/were recorded. Defaults to NULL (no override)
save_raw	Logical flag indicating whether to save_raw pupil data in addition to epoched data. Defaults to TRUE
html_report	Logical flag indicating whether to save out the eyeris preprocessing summary report as an HTML file. Defaults to TRUE
report_seed	Random seed for the plots that will appear in the report Defaults to 0. See plot() for a more detailed description
report_epoch_grouping_var_col	String name of grouping column to use for epoch-by-epoch diagnostic plots in an interactive rendered HTML report. Column name must exist (i.e., be a custom grouping variable name set within the metadata template of your epoch() call). Defaults to "matched_event", which all epoched data frames have as a valid column name. To disable these epoch-level diagnostic plots, set to NULL
verbose	A flag to indicate whether to print detailed logging messages. Defaults to TRUE. Set to FALSE to suppress messages about the current processing step and run silently
csv_enabled	Logical flag indicating whether to write CSV output files. Defaults to TRUE. Set to FALSE to disable CSV file generation, useful for large-scale cloud compute environments when using database storage only
db_enabled	Logical flag indicating whether to write data to a DuckDB database. Defaults to FALSE. When TRUE, creates or connects to a database for centralized data storage and querying
db_path	Database filename or path. Defaults to "eyeris-proj.eyerisdb". If just a filename, the database will be created in the derivatives/ directory. If a full path is provided, it will be used as specified
parallel_processing	Logical flag to manually enable parallel database processing. When TRUE, uses temporary databases to avoid concurrency issues. Defaults to FALSE (auto-detect based on environment variables)
merge_epochs	(Deprecated) This parameter is deprecated and will be ignored. All epochs are now saved as separate files following BIDS conventions. This parameter will be removed in a future version

`merge_runs` **(Deprecated)** This parameter is deprecated and will be ignored. All runs are now saved as separate files following BIDS conventions. This parameter will be removed in a future version

`pdf_report` **(Deprecated)** Use `html_report = TRUE` instead

Details

In the future, we intend for this function to save out the data in an official BIDS format for eyetracking data (see [the proposal currently under review here](#)). At this time, however, this function instead takes a more BIDS-inspired approach to organizing the output files for preprocessed pupil data.

Value

Invisibly returns NULL. Called for its side effects

See Also

    csv_enabled = FALSE, # disable CSV files
    db_enabled = TRUE # database storage only
  )

```

bin	<i>Bin pupil time series by averaging within time bins</i>
-----	--

Description

This function bins pupillometry data by dividing time into equal intervals and averaging the data within each bin. Unlike downsampling, binning averages data points within each time bin.

Usage

```
bin(eyeris, bins_per_second, method = "mean", call_info = NULL)
```

Arguments

eyeris	An object of class eyeris derived from load_asc()
bins_per_second	The number of bins to create per second of data
method	The binning method: "mean" (default) or "median"
call_info	A list of call information and parameters. If not provided, it will be generated from the function call. Defaults to NULL

Details

Binning divides one second of pupillary data into X bins and averages pupillometry data around each bin center. The resulting time points will be: $1/2X$, $3/2X$, $5/2X$, ..., etc. where X is the number of bins per second.

This approach is commonly used in pupillometry research to study temporal dynamics of pupil dilatory response; however, it should be used with caution (as averaging within bins can distort the pupillary dynamics).

Value

An eyeris object with binned data and updated sampling rate

Note

This function is part of the `glassbox()` preprocessing pipeline and is not intended for direct use in most cases. Provide parameters via `bin = list(...)`.

Advanced users may call it directly if needed.

See Also

`glassbox()` for the recommended way to run this step as part of the full `eyeris` `glassbox` preprocessing pipeline `downsample()` for downsampling functionality

For a complete, end-to-end reference pipeline that demonstrates how all `eyeris` preprocessing functions are chained together in practice, see the "Building Blocks Under the Hood" section of the *Anatomy of an `eyeris` Object* vignette — `vignette("anatomy", package = "eyeris")` — as well as the *Complete Pupillometry Pipeline Walkthrough* vignette: `vignette("complete-pipeline", package = "eyeris")`.

Examples

```
demo_data <- eyelink_asc_demo_dataset()

# bin data into 10 bins per second using the (default) "mean" method
demo_data |>
  eyeris::glassbox(bin = list(bins_per_second = 10, method = "mean")) |>
  plot(seed = 0)
```

boilerplate

Generate a reproducible, copy-and-paste-ready methods boilerplate

Description

Auto-generates human-readable, "fMRIPrep-style" methods-section boilerplate text that describes – in plain prose – the exact preprocessing workflow that was run on an `eyeris` object. Because every `eyeris` preprocessing step records its own call stack and parameters (in `eyeris$params`), the pipeline is able to self-document precisely what it did to your data, ready to paste directly into the methods section of a manuscript.

This reinforces the workflow-level transparency at the heart of the `eyeris` "glassbox" philosophy: the code that ran and the prose that describes it are generated from one and the same source of truth.

Usage

```
boilerplate(
  eyeris,
  version = NULL,
  include_citation = TRUE,
  include_license = TRUE
)
```

Arguments

<code>eyeris</code>	An object of class <code>eyeris</code> (e.g., the output of <code>glassbox()</code>). Binocular objects are supported.
<code>version</code>	Optional character string giving the <code>eyeris</code> version to cite in the boilerplate. Defaults to <code>NULL</code> , in which case the currently installed <code>eyeris</code> version is used.

```
include_citation
    Logical. Whether to append a formatted citation for eyeris. Defaults to TRUE.
include_license
    Logical. Whether to append the Creative Commons CC BY 4.0 license note
    telling users it is safe to paste the text into a manuscript as long as they cite
    eyeris for attribution. Defaults to TRUE.
```

Details

The generated text walks the recorded pipeline steps in the canonical order in which `eyeris` applies them (`load_asc -> deblink -> detransient -> interpolate -> lpfilt -> downsample/bin -> detrend -> zscore -> epoch`) and emits one sentence per step, substituting in the actual parameter values that were used. Steps that were skipped are omitted, and any custom (user-supplied) pipeline extensions are appended at the end so that multi-step and non-default pipelines are described faithfully. Multi-block (multi-run) and binocular recordings are handled automatically.

The boilerplate also references the per-run, machine-readable `.json` metadata sidecar that `eyeris` writes for every run (`source/logs/run-XX_metadata.json`), which together with the reported package version is sufficient to reproduce the pipeline exactly.

License & attribution. The auto-generated boilerplate text is licensed under the Creative Commons Attribution 4.0 International (CC BY 4.0) license (<https://creativecommons.org/licenses/by/4.0/>). It is explicitly safe to copy and paste the generated Markdown content directly into your manuscript, provided that you give appropriate credit by citing `eyeris` (run `citation("eyeris")` for the reference); including that citation in your references satisfies the attribution requirement. This mirrors the approach taken by fMRIPrep and other reproducible-pipeline tools.

When you run `bidsify()` (or `glassbox()` with reporting enabled), this same boilerplate is embedded in the diagnostic HTML report and written to `derivatives/.../source/logs/` as a standalone Markdown file.

Value

A length-one character string of Markdown-formatted methods boilerplate (invisibly classed as `eyeris_boilerplate` so it prints nicely at the console). The raw string can be passed to `base::cat()`, `base::writeLines()`, or embedded directly in a report.

See Also

`glassbox()`, `bidsify()`

Examples

```
demo_data <- eyelink_asc_demo_dataset()

eyeris_obj <- demo_data |>
  eyeris::glassbox(verbose = FALSE)

# print the copy-and-paste-ready methods boilerplate
boilerplate(eyeris_obj)

# capture it as plain Markdown text (e.g., to write to a file)
```

```
methods_md <- boilerplate(eyeris_obj)
cat(methods_md)
```

deblink

NA-pad blink events / missing data

Description

Deblinking (a.k.a. NA-padding) of time series data. The intended use of this method is to remove blink-related artifacts surrounding periods of missing data. For instance, when an individual blinks, there are usually rapid decreases followed by increases in pupil size, with a chunk of data missing in-between these 'spike'-looking events. The deblinking procedure here will NA-pad each missing data point by your specified number of ms.

Usage

```
deblink(eyeris, extend = 50, call_info = NULL)
```

Arguments

eyeris	An object of class <code>eyeris</code> derived from <code>load_asc()</code>
extend	Either a single number indicating the number of milliseconds to pad forward/backward around each missing sample, or, a vector of length two indicating different numbers of milliseconds pad forward/backward around each missing sample, in the format <code>c(backward, forward)</code>
call_info	A list of call information and parameters. If not provided, it will be generated from the function call

Details

This function is automatically called by `glassbox()` by default. If needed, customize the parameters for `deblink` by providing a parameter list. Use `glassbox(deblink = FALSE)` to disable this step as needed.

Users should prefer using `glassbox()` rather than invoking this function directly unless they have a specific reason to customize the pipeline manually.

Value

An `eyeris` object with a new column: `pupil_raw_{...}_deblink`

Note

This function is part of the `glassbox()` preprocessing pipeline and is not intended for direct use in most cases. Provide parameters via `deblink = list(...)`.

Advanced users may call it directly if needed.

See Also

`glassbox()` for the recommended way to run this step as part of the full `eyeris` `glassbox` preprocessing pipeline

For a complete, end-to-end reference pipeline that demonstrates how all `eyeris` preprocessing functions are chained together in practice, see the "Building Blocks Under the Hood" section of the *Anatomy of an `eyeris` Object* vignette — `vignette("anatomy", package = "eyeris")` — as well as the *Complete Pupillometry Pipeline Walkthrough* vignette: `vignette("complete-pipeline", package = "eyeris")`.

Examples

```
demo_data <- eyelink_asc_demo_dataset()

# 50 ms in both directions (the default)
demo_data |>
  eyeris::glassbox(deblink = list(extend = 50)) |>
  plot(seed = 0)

# 40 ms backward, 50 ms forward
demo_data |>
  # set deblink to FALSE (instead of a list of params)
  # to skip step (not recommended)
  eyeris::glassbox(deblink = list(extend = c(40, 50))) |>
  plot(seed = 0)
```

detransient

Remove pupil samples that are physiologically unlikely

Description

The intended use of this method is for removing pupil samples that emerge more quickly than would be physiologically expected. This is accomplished by rejecting samples that exceed a "speed"-based threshold (i.e., median absolute deviation from sample-to-sample). This threshold is computed based on the constant `n`, which defaults to the value 16.

Usage

```
detransient(eyeris, n = 16, mad_thresh = NULL, call_info = NULL)
```

Arguments

<code>eyeris</code>	An object of class <code>eyeris</code> derived from <code>load_asc()</code>
<code>n</code>	A constant used to compute the median absolute deviation (MAD) threshold. Defaults to 16

mad_thresh Default NULL. This parameter provides alternative options for handling edge cases where the computed properties here within `detransient()` *mad_val* and *median_speed* are very small. For example, if

$$mad_val = 0 \quad \text{and} \quad median_speed = 1,$$

then, with the default multiplier $n = 16$,

$$mad_thresh = median_speed + (n \times mad_val) = 1 + (16 \times 0) = 1.$$

In this situation, any speed $p_i \geq 1$ would be flagged as a transient, which might be overly sensitive. To reduce this sensitivity, two possible adjustments are available:

1. If *mad_thresh* = 1, the transient detection criterion is modified from

$$p_i \geq mad_thresh$$

to

$$p_i > mad_thresh.$$

2. If *mad_thresh* is very small, the user may manually adjust the sensitivity by supplying an alternative threshold value here directly via this *mad_thresh* parameter.

call_info A list of call information and parameters. If not provided, it will be generated from the function call. Defaults to NULL

Details

This function is automatically called by `glassbox()` by default. If needed, customize the parameters for `detransient` by providing a parameter list. Use `glassbox(detransient = FALSE)` to disable this step as needed.

Users should prefer using `glassbox()` rather than invoking this function directly unless they have a specific reason to customize the pipeline manually.

Computed properties:

- **pupil_speed:** Compute speed of pupil by approximating the derivative of x (pupil) with respect to y (time) using finite differences.
 - Let $x = (x_1, x_2, \dots, x_n)$ and $y = (y_1, y_2, \dots, y_n)$ be two numeric vectors with $n \geq 2$; then, the finite differences are computed as:

$$\delta_i = \frac{x_{i+1} - x_i}{y_{i+1} - y_i}, \quad i = 1, 2, \dots, n-1.$$

- This produces an output vector $p = (p_1, p_2, \dots, p_n)$ defined by:
 - * For the first element:

$$p_1 = |\delta_1|,$$

- * For the last element:

$$p_n = |\delta_{n-1}|,$$

* For the intermediate elements ($i = 2, 3, \dots, n - 1$):

$$p_i = \max\{|\delta_{i-1}|, |\delta_i|\}.$$

- **median_speed:** The median of the computed `pupil_speed`:

$$\text{median_speed} = \text{median}(p)$$

- **mad_val:** The median absolute deviation (MAD) of `pupil_speed` from the median:

$$\text{mad_val} = \text{median}(|p - \text{median_speed}|)$$

- **mad_thresh:** A threshold computed from the median speed and the MAD, using a constant multiplier n (default value: 16):

$$\text{mad_thresh} = \text{median_speed} + (n \times \text{mad_val})$$

Value

An `eyeris` object with a new column in time series: `pupil_raw_{...}_detransient`

Note

This function is part of the `glassbox()` preprocessing pipeline and is not intended for direct use in most cases. Provide parameters via `detransient = list(...)`.

Advanced users may call it directly if needed.

See Also

[glassbox\(\)](#) for the recommended way to run this step as part of the full `eyeris` `glassbox` preprocessing pipeline.

For a complete, end-to-end reference pipeline that demonstrates how all `eyeris` preprocessing functions are chained together in practice, see the "Building Blocks Under the Hood" section of the *Anatomy of an eyeris Object* vignette — `vignette("anatomy", package = "eyeris")` — as well as the *Complete Pupillometry Pipeline Walkthrough* vignette: `vignette("complete-pipeline", package = "eyeris")`.

Examples

```
demo_data <- eyelink_asc_demo_dataset()

demo_data |>
  eyeris::glassbox(
    detransient = list(n = 16) # set to FALSE to skip step (not recommended)
  ) |>
  plot(seed = 0)
```

detrend	<i>Detrend the pupil time series</i>
---------	--------------------------------------

Description

Linearly detrend_pupil data by fitting a linear model of `pupil_data ~ time`, and return the fitted betas and the residuals (`pupil_data - fitted_values`).

Usage

```
detrend(eyeris, call_info = NULL)
```

Arguments

<code>eyeris</code>	An object of class <code>eyeris</code> derived from <code>load_asc()</code>
<code>call_info</code>	A list of call information and parameters. If not provided, it will be generated from the function call. Defaults to <code>NULL</code>

Details

This function is automatically called by `glassbox()` if `detrend = TRUE`.

Users should prefer using `glassbox()` rather than invoking this function directly unless they have a specific reason to customize the pipeline manually.

Value

An `eyeris` object with two new columns in time series: `detrend_fitted_betas`, and `pupil_raw_{...}_detrend`

Note

This function is part of the `glassbox()` preprocessing pipeline and is not intended for direct use in most cases. Use `glassbox(detrend = TRUE)`.

Advanced users may call it directly if needed.

See Also

`glassbox()` for the recommended way to run this step as part of the full `eyeris` `glassbox` preprocessing pipeline

For a complete, end-to-end reference pipeline that demonstrates how all `eyeris` preprocessing functions are chained together in practice, see the "Building Blocks Under the Hood" section of the *Anatomy of an eyeris Object* vignette — `vignette("anatomy", package = "eyeris")` — as well as the *Complete Pupillometry Pipeline Walkthrough* vignette: `vignette("complete-pipeline", package = "eyeris")`.

Examples

```
demo_data <- eyelink_asc_demo_dataset()

demo_data |>
  eyeris::glassbox(detrend = TRUE) |> # set to FALSE to skip step (default)
  plot(seed = 0)
```

downsample

*Downsample pupil time series with anti-aliasing filtering***Description**

This function downsamples pupillometry data by applying an anti-aliasing filter before decimation. Unlike binning, downsampling preserves the original temporal dynamics without averaging within bins.

Usage

```
downsample(
  eyeris,
  target_fs,
  plot_freqz = FALSE,
  rp = 1,
  rs = 35,
  call_info = NULL
)
```

Arguments

<code>eyeris</code>	An object of class <code>eyeris</code> derived from <code>load_asc()</code> .
<code>target_fs</code>	The target sampling frequency in Hz after downsampling.
<code>plot_freqz</code>	Boolean flag for displaying filter frequency response (default FALSE).
<code>rp</code>	Passband ripple in dB (default 1).
<code>rs</code>	Stopband attenuation in dB (default 35).
<code>call_info</code>	A list of call information and parameters. If not provided, it will be generated from the function call.

Details

Downsampling reduces the sampling frequency by decimating data points. The function automatically designs an anti-aliasing filter using the `lpfilt()` function with carefully chosen parameters:

- ws (stopband frequency) = $Fs_{new} / 2$ (Nyquist freq of new sampling rate)
- wp (passband frequency) = $ws - \max(5, Fs_{nq} * 0.2)$
- An error is raised if $wp < 4$ to prevent loss of pupillary responses

The resulting time points will be: 0, 1/X, 2/X, 3/X, ..., etc. where X is the new sampling frequency.

Value

An `eyeris` object with downsampled data and updated sampling rate.

Note

This function is part of the `glassbox()` preprocessing pipeline and is not intended for direct use in most cases. Provide parameters via `downsample = list(...)`.

Advanced users may call it directly if needed.

See Also

`glassbox()` for the recommended way to run this step as part of the full `eyeris` `glassbox` preprocessing pipeline. `bin()` for binning functionality.

For a complete, end-to-end reference pipeline that demonstrates how all `eyeris` preprocessing functions are chained together in practice, see the "Building Blocks Under the Hood" section of the *Anatomy of an eyeris Object* vignette — `vignette("anatomy", package = "eyeris")` — as well as the *Complete Pupillometry Pipeline Walkthrough* vignette: `vignette("complete-pipeline", package = "eyeris")`.

Examples

```
demo_data <- eyelink_asc_demo_dataset()

# downsample pupil data recorded at 1000 Hz to 100 Hz with the default params
demo_data |>
  eyeris::glassbox(downsample = list(target_fs = 100)) |>
  plot(seed = 0)
```

epoch	<i>Epoch (and baseline) pupil data based on custom event message structure</i>
-------	--

Description

Intended to be used as the final preprocessing step. This function creates data epochs of either fixed or dynamic durations with respect to provided events and time limits, and also includes an intuitive metadata parsing feature where additional trial data embedded within event messages can easily be identified and joined into the resulting epoched data frames.

Usage

```
epoch(
  eyeris,
  events,
  limits = NULL,
  label = NULL,
```

```

baseline = FALSE,
baseline_type = c("sub", "div"),
baseline_events = NULL,
baseline_period = NULL,
hz = NULL,
verbose = TRUE,
call_info = NULL,
calc_baseline = deprecated(),
apply_baseline = deprecated()
)

```

Arguments

- | | |
|--------|--|
| eyeris | An object of class <code>eyeris</code> derived from <code>load_asc()</code> |
| events | <p>Either (1) a single string representing the event message to perform trial extraction around, using specified <code>limits</code> to center the epoch around or no <code>limits</code> (which then just grabs the data epochs between each subsequent event string of the same type); (2) a vector containing both <code>start</code> and <code>end</code> event message strings – here, <code>limits</code> will be ignored and the duration of each trial epoch will be the number of samples between each matched <code>start</code> and <code>end</code> event message pair; or (3) a list of 2 data frames that manually specify start/end event timestamp-message pairs to pull out of the raw time series data – here, it is required that each raw timestamp and event message be provided in the following format:</p> <pre>list(data.frame(time = c(...), msg = c(...)), # start events data.frame(time = c(...), msg = c(...)), # end events 1 # block number)</pre> <p>where the first <code>data.frame</code> indicates the <code>start</code> event timestamp and message string pairs, and the second <code>data.frame</code> indicates the <code>end</code> event timestamp and message string pairs. Additionally, manual epoching only works with 1 block at a time for event-modes 2 and 3; thus, please be sure to explicitly indicate the block number in your input list (for examples, see above as well as example #9 below for more details)</p> <p>For event-modes 1 and 2, the way in which you pass in the event message string must conform to a standardized protocol so that <code>eyeris</code> knows how to find your events and (optionally) parse any included metadata into the tidy epoch data outputs. You have two primary choices: either (a) specify a string followed by a <code>*</code> wildcard expression (e.g., <code>"PROBE_START"</code>), which will match any messages that have <code>"PROBE_START ..."</code> (... referring to potential metadata, such as trial number, stim file, etc.); or (b) specify a string using the <code>eyeris</code> syntax: (e.g., <code>"PROBE_{type}_{trial}"</code>), which will match the messages that follow a structure like this <code>"PROBE_START_1"</code> and <code>"PROBE_STOP_1"</code>, and generate two additional metadata columns: <code>type</code> and <code>trial</code>, which would contain the following values based on these two example strings: <code>type: ('START', 'STOP')</code>, and <code>trial: (1, 1)</code></p> |
| limits | A vector of 2 values (<code>start</code> , <code>end</code>) in seconds, indicating where trial extraction should occur centered around any given <code>start</code> message string in the <code>events</code> parameter |

label	An (optional) string you can provide to customize the name of the resulting <code>eyeris</code> class object containing the epoched data frame. If left as NULL (default), then list item will be called <code>epoch_xyz</code> , where <code>xyz</code> will be a sanitized version of the original <code>start</code> event string you provided for matching. If you choose to specify a label here, then the resulting list object name will take the form: <code>epoch_label</code> . Warning: if no label is specified and there are no event message strings to sanitize, then you may obtain a strange-looking epoch list element in your output object (e.g., <code>\$epoch_</code>, or <code>\$epoch_nana</code>, etc.). The data should still be accessible within this nested lists, however, to avoid ambiguous list objects, we recommend you provide an epoch label here to be safe
baseline	(New) A single parameter that controls baseline correction. Set to TRUE to both calculate and apply baseline correction, or FALSE to skip it. This replaces the deprecated <code>calc_baseline</code> and <code>apply_baseline</code> parameters
baseline_type	Whether to perform <i>subtractive</i> (sub) or <i>divisive</i> (div) baseline correction. Defaults to sub
baseline_events	Similar to <code>events</code> , <code>baseline_events</code> , you can supply either (1) a single string representing the event message to center the baseline calculation around, as indicated by <code>baseline_period</code> ; or (2) a single vector containing both a start and an end event message string – here, <code>baseline_period</code> will be ignored and the duration of each baseline period that the mean will be calculated on will be the number of samples between each matched start and end event message pair, as opposed to a specified fixed duration (as described in 1). Please note, providing a list of trial-level start/end message pairs (like in the <code>events</code> parameter) to manually indicate unique start/end chunks for baselining is currently unsupported. Though, we intend to add this feature in a later version of <code>eyeris</code> , given it likely won't be a heavily utilized / in demand feature.
baseline_period	A vector of 2 values (start, end) in seconds, indicating the window of data that will be used to perform the baseline correction, which will be centered around the single string "start" message string provided in <code>baseline_events</code> . Again, <code>baseline_period</code> will be ignored if both a "start" and "end" message string are provided to the <code>baseline_events</code> argument
hz	Data sampling rate. If not specified, will use the value contained within the tracker's metadata
verbose	A flag to indicate whether to print detailed logging messages Defaults to TRUE. Set to False to suppress messages about the current processing step and run silently
call_info	A list of call information and parameters. If not provided, it will be generated from the function call
calc_baseline	(Deprecated) Use <code>baseline</code> instead
apply_baseline	(Deprecated) Use <code>baseline</code> instead

Value

An `eyeris` object with a new nested list of data frames: `$epoch_*`. The epochs are organized hierarchically by block and preprocessing step. Each epoch contains the pupil time series data for

the specified time window around each event message, along with metadata about the event.

When using `bidsify()` to export the data, filenames will include both epoch and baseline event information for clarity.

`lifecycle::deprecate_warn()`

Examples

```
demo_data <- eyelink_asc_demo_dataset()
eye_preproc <- eyeris::glassbox(demo_data)

# example 1: select 1 second before/after matched event message "PROBE*"
eye_preproc |>
  eyeris::epoch(events = "PROBE*", limits = c(-1, 1))

# example 2: select all samples between each trial
eye_preproc |>
  eyeris::epoch(events = "TRIALID {trial}")

# example 3: grab the 1 second following probe onset
eye_preproc |>
  eyeris::epoch(
    events = "PROBE_START_{trial}",
    limits = c(0, 1)
  )

# example 4: 1 second prior to and 1 second after probe onset
eye_preproc |>
  eyeris::epoch(
    events = "PROBE_START_{trial}",
    limits = c(-1, 1),
    label = "prePostProbe" # custom epoch label name
  )

# example 5: manual start/end event pairs
# note: here, the `msg` column of each data frame is optional
eye_preproc |>
  eyeris::epoch(
    events = list(
      data.frame(time = c(11334491), msg = c("TRIALID 22")), # start events
      data.frame(time = c(11337158), msg = c("RESPONSE_22")), # end events
      1 # block number
    ),
    label = "example5"
  )

# example 6: manual start/end event pairs
# note: set `msg` to NA if you only want to pass in start/end timestamps
eye_preproc |>
  eyeris::epoch(
```

```

events = list(
  data.frame(time = c(11334491), msg = NA), # start events
  data.frame(time = c(11337158), msg = NA), # end events
  1 # block number
),
label = "example6"
)

## examples with baseline arguments enabled

# example 7: use mean of 1-s preceding "PROBE_START" (i.e. "DELAY_STOP")
# to perform subtractive baselining of the 1-s PROBE epochs.
eye_preproc |>
  eyeris::epoch(
    events = "PROBE_START_{trial}",
    limits = c(0, 1), # grab 0 seconds prior to and 1 second post PROBE event
    label = "prePostProbe", # custom epoch label name
    baseline = TRUE, # calculate and apply baseline correction
    baseline_type = "sub", # "sub"tractive baseline calculation is default
    baseline_events = "DELAY_STOP_*",
    baseline_period = c(-1, 0)
  )

# example 8: use mean of time period between set start/end event messages
# (i.e. between "DELAY_START" and "DELAY_STOP"). In this case, the
# `baseline_period` argument will be ignored since both a "start" and "end"
# message string are provided to the `baseline_events` argument.
eye_preproc |>
  eyeris::epoch(
    events = "PROBE_START_{trial}",
    limits = c(0, 1), # grab 0 seconds prior to and 1 second post PROBE event
    label = "prePostProbe", # custom epoch label name
    baseline = TRUE, # calculate and apply baseline correction
    baseline_type = "sub", # "sub"tractive baseline calculation is default
    baseline_events = c(
      "DELAY_START_*",
      "DELAY_STOP_*"
    )
  )

# example 9: additional (potentially helpful) example
start_events <- data.frame(
  time = c(11334491, 11338691),
  msg = c("TRIALID 22", "TRIALID 23")
)
end_events <- data.frame(
  time = c(11337158, 11341292),
  msg = c("RESPONSE_22", "RESPONSE_23")
)
block_number <- 1

eye_preproc |>
  eyeris::epoch(

```

```
events = list(start_events, end_events, block_number),  
label   = "example9"  
)
```

eyelink_asc_binocular_demo_dataset

Access example EyeLink .asc binocular mock dataset file provided by the eyeris package.

Description

Returns the file path to the demo binocular .asc EyeLink pupil data file included in the eyeris package.

Usage

```
eyelink_asc_binocular_demo_dataset()
```

Details

This dataset is a mock dataset trimmed from a larger data file. The original data file was obtained from: https://github.com/scott-huberty/eyelinkio/blob/main/src/eyelinkio/tests/data/test_raw_binocular.edf

Value

A character string giving the full file path to the demo .asc EyeLink pupil data file

Examples

```
path_to_binocular_demo_dataset <- eyelink_asc_binocular_demo_dataset()  
print(path_to_binocular_demo_dataset)
```

eyelink_asc_demo_dataset

Access example EyeLink .asc demo dataset file provided by the eyeris package.

Description

Returns the file path to the demo .asc EyeLink pupil data file included in the eyeris package.

Usage

```
eyelink_asc_demo_dataset()
```

Value

A character string giving the full file path to the demo .asc EyeLink pupil data file

Examples

```
path_to_demo_dataset <- eyelink_asc_demo_dataset()
print(path_to_demo_dataset)
```

eyellogger	<i>Run eyeris commands with automatic logging of R console's stdout and stderr</i>
------------	--

Description

This utility function evaluates `eyeris` commands while automatically capturing and recording both standard output (`stdout`) and standard error (`stderr`) to timestamped log files in your desired log directory.

Usage

```
eyellogger(
  eyeris_cmd,
  log_dir = file.path(tempdir(), "eyeris_logs"),
  timestamp_format = "%Y%m%d_%H%M%S"
)
```

Arguments

<code>eyeris_cmd</code>	An <code>eyeris</code> command, wrapped in <code>{}</code> if multiline
<code>log_dir</code>	Character path to the desired log directory. Is set to the temporary directory given by <code>tempdir()</code> by default
<code>timestamp_format</code>	Format string passed to <code>format(Sys.time())</code> for naming the log files. Defaults to <code>"%Y%m%d_%H%M%S"</code>

Details

Each run produces two log files:

- `<timestamp>.out`: records all console output
- `<timestamp>.err`: records all warnings and errors

Value

The result of the evaluated `eyeris` command (invisibly)

Examples

```
eyelgger({
  message("eyeris `glassbox()` completed successfully.")
  warning("eyeris `glassbox()` completed with warnings.")
  print("some eyeris-related information.")
})

eyelgger({
  glassbox(eyelink_asc_demo_dataset(), interactive_preview = FALSE)
}, log_dir = file.path(tempdir(), "eyeris_logs"))
```

eyeris_color_palette *Default color palette for eyeris plotting functions*

Description

A custom color palette designed for visualizing pupil data preprocessing steps. This palette is based on the RColorBrewer Set1 palette and provides distinct, visually appealing colors for different preprocessing stages.

Usage

```
eyeris_color_palette()
```

Details

The palette includes 7 colors optimized for:

- High contrast and visibility
- Colorblind-friendly design
- Consistent visual hierarchy across preprocessing steps
- Professional appearance in reports and publications

Colors are designed to work well with both light and dark backgrounds and maintain readability when overlaid in time series plots.

Value

A character vector of 7 hex color codes representing the default eyeris color palette

Examples

```
# get the default color palette
colors <- eyeris_color_palette()
print(colors)

# use in a plot
plot(1:7, 1:7, col = colors, pch = 19, cex = 3)
```

eyeris_db_collect	<i>Extract and aggregate eyeris data across subjects from database</i>
-------------------	--

Description

A comprehensive wrapper function that simplifies extracting eyeris data from the database. Provides easy one-liner access to aggregate data across multiple subjects for each data type, without requiring SQL knowledge.

Usage

```
eyeris_db_collect(
  bids_dir,
  db_path = "my-project",
  subjects = NULL,
  data_types = NULL,
  sessions = NULL,
  tasks = NULL,
  epoch_labels = NULL,
  eye_suffixes = NULL,
  verbose = TRUE
)
```

Arguments

bids_dir	Path to the BIDS directory containing the database
db_path	Database name (defaults to "my-project", becomes "my-project.eyerisdb")
subjects	Vector of subject IDs to include. If NULL (default), includes all subjects
data_types	Vector of data types to extract. If NULL (default), extracts all available types. Valid types: "blinks", "events", "timeseries", "epochs", "epoch_summary", "run_confounds", "confounds_events", "confounds_summary"
sessions	Vector of session IDs to include. If NULL (default), includes all sessions
tasks	Vector of task names to include. If NULL (default), includes all tasks
epoch_labels	Vector of epoch labels to include. If NULL (default), includes all epochs. Only applies to epoch-related data types
eye_suffixes	Vector of eye suffixes to include. If NULL (default), includes all eyes. Typically c("eye-L", "eye-R") for binocular data
verbose	Logical. Whether to print progress messages (default TRUE)

Value

A named list of data frames, one per data type

Examples

```

demo_data <- eyelink_asc_demo_dataset()

demo_data |>
  eyeris::glassbox() |>
  eyeris::epoch(
    events = "PROBE_{startstop}_{trial}",
    limits = c(-1, 1),
    label = "prePostProbe"
  ) |>
  eyeris::bidsify(
    bids_dir = tempdir(),
    participant_id = "001",
    session_num = "01",
    task_name = "assocret",
    run_num = "03", # override default run-01 (block_1) to use run-03 instead
    db_enabled = TRUE # enable database storage
  )

# extract all data for all subjects (returns list of data frames)
all_data <- eyeris_db_collect(tempdir())

# view available data types
names(all_data)

# access specific data type
blinks_data <- all_data$blinks
epochs_data <- all_data$epochs

# extract specific subjects and data types
subset_data <- eyeris_db_collect(
  bids_dir = tempdir(),
  subjects = c("001"),
  data_types = c("blinks", "epochs", "timeseries")
)

# extract epoch data for specific epoch label
epoch_data <- eyeris_db_collect(
  bids_dir = tempdir(),
  data_types = "epochs",
  epoch_labels = "prepostprobe"
)

```

Description

User-friendly function to connect to an existing eyeris project database. This function provides easy access for users to query their eyeris data.

Usage

```
eyeris_db_connect(bids_dir, db_path = "my-project")
```

Arguments

bids_dir	Path to the BIDS directory containing the database
db_path	Database name (defaults to "my-project", becomes "my-project.eyerisdb") If just a filename, will look in derivatives/ directory. If includes path, will use as provided.

Value

Database connection object for use with other eyeris database functions

Examples

```
# step 1: create a database using bidsify with db_enabled = TRUE
# (This example assumes you have already run bidsify to create a database)

# temp dir for testing
temp_dir <- tempdir()

# step 2: connect to eyeris DB (will fail gracefully if no DB exists)
tryCatch({
  con <- eyeris_db_connect(temp_dir)

  tables <- eyeris_db_list_tables(con)

  # read timeseries data for a specific subject
  data <- eyeris_db_read(con, data_type = "timeseries", subject = "001")

  # close connection when done
  eyeris_db_disconnect(con)
}, error = function(e) {
  message("No eyeris DB found - create one first with bidsify(db_enabled = TRUE)")
})
```

eyeris_db_disconnect	<i>Disconnect from eyeris database (user-facing)</i>
----------------------	--

Description

User-friendly function to disconnect from the eyeris project database.

Usage

```
eyeris_db_disconnect(con)
```

Arguments

con	Database connection object
-----	----------------------------

Value

Logical indicating success

eyeris_db_list_tables	<i>List available tables in eyeris database</i>
-----------------------	---

Description

Lists all tables in the eyeris project database with optional filtering.

Usage

```
eyeris_db_list_tables(con, data_type = NULL, subject = NULL)
```

Arguments

con	Database connection
data_type	Optional filter by data type
subject	Optional filter by subject ID

Value

Character vector of table names

eyeris_db_read	<i>Read eyeris data from database</i>
----------------	---------------------------------------

Description

Reads eyeris data from the project database with dplyr-style interface.

Usage

```
eyeris_db_read(  
  con,  
  data_type = NULL,  
  subject = NULL,  
  session = NULL,  
  task = NULL,  
  run = NULL,  
  eye_suffix = NULL,  
  epoch_label = NULL,  
  table_name = NULL  
)
```

Arguments

con	Database connection
data_type	Type of data to read ("timeseries", "epochs", "epoch_timeseries", "epoch_summary", "events", "blinks")
subject	Optional subject ID filter
session	Optional session ID filter
task	Optional task name filter
run	Optional run number filter
eye_suffix	Optional eye suffix filter
epoch_label	Optional epoch label filter (for epoched data)
table_name	Exact table name (overrides other parameters)

Value

Data frame with requested data

`eyeris_db_reconstruct_from_chunks`*Reconstruct eyerisdb from chunked files*

Description

Merges multiple chunked eyerisdb files back into a single database file. Uses the reconstruction metadata file created by `eyeris_db_split_for_sharing()` to ensure proper reconstruction.

Usage

```
eyeris_db_reconstruct_from_chunks(  
  chunked_dir,  
  output_path,  
  reconstruction_file = NULL,  
  verbose = TRUE  
)
```

Arguments

<code>chunked_dir</code>	Directory containing the chunked database files and reconstruction metadata
<code>output_path</code>	Full path for the reconstructed database (e.g., <code>"/path/to/reconstructed.eyerisdb"</code>)
<code>reconstruction_file</code>	Path to the reconstruction metadata JSON file. If NULL (default), searches for <code>"*_reconstruction_info.json"</code> in <code>chunked_dir</code>
<code>verbose</code>	Whether to print progress messages (default: TRUE)

Value

List containing information about the reconstruction process

Examples

```
## Not run:  
# Reconstruct database from chunked files  
reconstruction_info <- eyeris_db_reconstruct_from_chunks(  
  chunked_dir = "/path/to/chunked_db/project-name",  
  output_path = "/path/to/reconstructed-project.eyerisdb"  
)  
  
# Specify custom reconstruction file location  
reconstruction_info <- eyeris_db_reconstruct_from_chunks(  
  chunked_dir = "/path/to/chunked_db/project-name",  
  output_path = "/path/to/reconstructed-project.eyerisdb",  
  reconstruction_file = "/path/to/custom_reconstruction_info.json"  
)  
  
## End(Not run)
```

eyeris_db_split_for_sharing

Split eyerisdb for data sharing and distribution

Description

Creates multiple smaller eyerisdb files from a single large database for easier distribution via platforms with file size limits (GitHub, OSF, data repositories, etc.). Data can be chunked by data type, by number of chunks, or by maximum file size. Includes metadata to facilitate reconstruction of the original database.

Usage

```
eyeris_db_split_for_sharing(
  bids_dir,
  db_path = "my-project",
  output_dir = NULL,
  chunk_strategy = "by_data_type",
  n_chunks = 4,
  max_chunk_size_mb = 100,
  data_types = NULL,
  group_by_epoch_label = TRUE,
  include_metadata = TRUE,
  verbose = TRUE
)
```

Arguments

bids_dir	Path to the BIDS directory containing the source database
db_path	Source database name (defaults to "my-project", becomes "my-project.eyerisdb")
output_dir	Directory to save chunked databases (defaults to bids_dir/derivatives/chunked_db)
chunk_strategy	Strategy for chunking: "by_data_type", "by_count", or "by_size" (default: "by_data_type")
n_chunks	Number of chunks to create when chunk_strategy = "by_count" (default: 4)
max_chunk_size_mb	Maximum size per chunk in MB when chunk_strategy = "by_size" (default: 100)
data_types	Vector of data types to include. If NULL (default), includes all available
group_by_epoch_label	If TRUE (default), processes epoch-related data types separately by epoch label
include_metadata	Whether to include eyeris metadata columns in chunked databases (default: TRUE)
verbose	Whether to print progress messages (default: TRUE)

Value

List containing information about created chunked databases and reconstruction instructions

Examples

```
## Not run:
# These examples require an existing eyeris database

# Chunk by data type (each data type gets its own database file)
chunk_info <- eyeris_db_split_for_sharing(
  bids_dir = "/path/to/bids",
  db_path = "large-project",
  chunk_strategy = "by_data_type"
)

# Chunk into 6 files by count
chunk_info <- eyeris_db_split_for_sharing(
  bids_dir = "/path/to/bids",
  db_path = "large-project",
  chunk_strategy = "by_count",
  n_chunks = 6
)

# Chunk by size (max 50MB per file)
chunk_info <- eyeris_db_split_for_sharing(
  bids_dir = "/path/to/bids",
  db_path = "large-project",
  chunk_strategy = "by_size",
  max_chunk_size_mb = 50
)

## End(Not run)
```

eyeris_db_summary

Get summary statistics for eyeris database

Description

Provides a quick overview of the contents of an eyeris database, including available subjects, sessions, tasks, and data types.

Usage

```
eyeris_db_summary(bids_dir, db_path = "my-project", verbose = TRUE)
```

Arguments

<code>bids_dir</code>	Path to the BIDS directory containing the database
<code>db_path</code>	Database name (defaults to "my-project", becomes "my-project.eyerisdb")
<code>verbose</code>	Logical. Whether to print detailed output (default TRUE)

Value

A named list containing summary information about the database contents

Examples

```
demo_data <- eyelink_asc_demo_dataset()

demo_data |>
  eyeris::glassbox() |>
  eyeris::epoch(
    events = "PROBE_{startstop}_{trial}",
    limits = c(-1, 1),
    label = "prePostProbe"
  ) |>
  eyeris::bidsify(
    bids_dir = file.path(tempdir(), "my-cool-memory-project"),
    participant_id = "001",
    session_num = "01",
    task_name = "assocret",
    run_num = "03", # override default run-01 (block_1) to use run-03 instead
    db_enabled = TRUE,
    db_path = "my-cool-memory-study",
  )

# get database summary
summary <- eyeris_db_summary(
  file.path(
    tempdir(),
    "my-cool-memory-project"
  ),
  db_path = "my-cool-memory-study"
)

# view available subjects
summary$subjects

# view available data types
summary$data_types

# view table counts
summary$table_counts
```

eyeris_db_to_chunked_files

Export eyeris database to chunked files

Description

High-level wrapper function to export large eyeris databases to chunked CSV or Parquet files by data type. Uses chunked processing to handle very large datasets without memory issues.

Usage

```
eyeris_db_to_chunked_files(
  bids_dir,
  db_path = "my-project",
  output_dir = NULL,
  chunk_size = 1e+06,
  file_format = "csv",
  data_types = NULL,
  subjects = NULL,
  max_file_size_mb = 50,
  group_by_epoch_label = TRUE,
  verbose = TRUE
)
```

Arguments

bids_dir	Path to the BIDS directory containing the database
db_path	Database name (defaults to "my-project", becomes "my-project.eyerisdb")
output_dir	Directory to save output files (defaults to bids_dir/derivatives/eyerisdb_export)
chunk_size	Number of rows to process per chunk (default: 1000000)
file_format	Output format: "csv" or "parquet" (default: "csv")
data_types	Vector of data types to export. If NULL (default), exports all available
subjects	Vector of subject IDs to include. If NULL (default), includes all subjects
max_file_size_mb	Maximum file size in MB per output file (default: 50). When exceeded, automatically creates numbered files (e.g., data_01-of-03.csv, data_02-of-03.csv)
group_by_epoch_label	If TRUE (default), processes epoch-related data types separately by epoch label to reduce memory footprint and produce label-specific files. When FALSE, epochs with different labels are merged into single large files (not recommended).
verbose	Whether to print progress messages (default: TRUE)

Value

List containing information about exported files

Examples

```
## Not run:
# These examples require an existing eyeris database

# Export entire database to CSV files
if (file.exists(file.path(tempdir(), "derivatives", "large-project.eyerisdb"))) {
  export_info <- eyeris_db_to_chunked_files(
    bids_dir = tempdir(),
    db_path = "large-project",
    chunk_size = 50000,
    file_format = "csv"
  )
}

# Export specific data types to Parquet
if (file.exists(file.path(tempdir(), "derivatives", "large-project.eyerisdb"))) {
  export_info <- eyeris_db_to_chunked_files(
    bids_dir = tempdir(),
    db_path = "large-project",

    chunk_size = 75000
  )
}

## End(Not run)
```

eyeris_db_to_parquet *Split eyeris database into N parquet files by data type*

Description

Utility function that takes an eyerisdb DuckDB database and splits it into N reasonably sized parquet files for easy management with GitHub, downloading, and distribution. Data is first grouped by table type (timeseries, epochs, events, etc.) since each has different columnar structures, then each group is split into the specified number of files. Files are organized in folders matching the database name for easy identification.

Usage

```
eyeris_db_to_parquet(
  bids_dir,
  db_path = "my-project",
  n_files_per_type = 1,
  output_dir = NULL,
  max_file_size = 512,
  data_types = NULL,
  verbose = TRUE,
```

```

    include_metadata = TRUE,
    epoch_labels = NULL,
    group_by_epoch_label = TRUE
  )

```

Arguments

<code>bids_dir</code>	Path to the BIDS directory containing the database
<code>db_path</code>	Database name (defaults to "my-project", becomes "my-project.eyerisdb")
<code>n_files_per_type</code>	Number of parquet files to create per data type (default: 1)
<code>output_dir</code>	Directory to save parquet files (defaults to <code>bids_dir/derivatives/parquet</code>)
<code>max_file_size</code>	Maximum file size in MB per parquet file (default: 512) Used as a constraint when <code>n_files_per_type</code> would create files larger than this
<code>data_types</code>	Vector of data types to include. If NULL (default), includes all available. Valid types: "timeseries", "epochs", "epoch_summary", "events", "blinks", "confounds_*"
<code>verbose</code>	Whether to print progress messages (default: TRUE)
<code>include_metadata</code>	Whether to include eyeris metadata columns in output (default: TRUE)
<code>epoch_labels</code>	Optional character vector of epoch labels to include (e.g., "prepostprobe"). Only applies to epoch-related data types. If NULL, includes all labels.
<code>group_by_epoch_label</code>	If TRUE, processes epoch-related data types separately by epoch label to reduce memory footprint and produce label-specific parquet files (default: TRUE).

Value

List containing information about created parquet files

Database Safety

This function creates temporary tables during parquet export when the arrow package is not available. All temporary tables are automatically cleaned up, but if the process crashes, leftover tables may remain. The function checks for and warns about existing temporary tables before starting.

Examples

```

# create demo database
demo_data <- eyelink_asc_demo_dataset()
demo_data |>
  eyeris::glassbox() |>
  eyeris::epoch(
    events = "PROBE_{startstop}_{trial}",
    limits = c(-1, 1),
    label = "prePostProbe"
  ) |>
  eyeris::bidsify(
    bids_dir = tempdir(),

```

```

    participant_id = "001",
    session_num = "01",
    task_name = "memory",
    db_enabled = TRUE,
    db_path = "memory-task"
  )

# split into 3 parquet files per data type - creates memory-task/ folder
split_info <- eyeris_db_to_parquet(
  bids_dir = tempdir(),
  db_path = "memory-task",
  n_files_per_type = 3
)

# split with size constraint and specific data types using the same database
split_info <- eyeris_db_to_parquet(
  bids_dir = tempdir(),
  db_path = "memory-task",
  n_files_per_type = 5,
  max_file_size = 50, # max 50MB per file
  data_types = c("timeseries", "epochs", "events")
)

```

glassbox

The opinionated "glass box" eyeris pipeline

Description

This glassbox function (in contrast to a "black box" function where you run it and get a result but have no (or little) idea as to how you got from input to output) has a few primary benefits over calling each exported function from eyeris separately.

Usage

```

glassbox(
  file,
  interactive_preview = FALSE,
  preview_n = 3,
  preview_duration = 5,
  preview_window = NULL,
  verbose = TRUE,
  ...,
  confirm = deprecated(),
  num_previews = deprecated(),
  detrend_data = deprecated(),
  skip_detransient = deprecated()
)

```

Arguments

file	An SR Research EyeLink .asc file generated by the official EyeLink edf2asc command
interactive_preview	A flag to indicate whether to run the glassbox pipeline autonomously all the way through (set to FALSE by default), or to interactively provide a visualization after each pipeline step, where you must also indicate "(y)es" or "(n)o" to either proceed or cancel the current glassbox pipeline operation (set to TRUE)
preview_n	Number of random example "epochs" to generate for previewing the effect of each preprocessing step on the pupil time series
preview_duration	Time in seconds of each randomly selected preview
preview_window	The start and stop raw timestamps used to subset the preprocessed data from each step of the eyeris workflow for visualization. Defaults to NULL, meaning random epochs as defined by preview_n and preview_duration will be plotted. To override the random epochs, set preview_window here to a vector with relative start and stop times (in seconds), for example – c(5,6) – to indicate the raw data from 5-6 secs on data that were recorded at 1000 Hz). Note, the start/stop time values indicated here are in seconds because eyeris automatically computes the indices for the supplied range of seconds using the \$info\$sample.rate metadata in the eyeris S3 class object
verbose	A logical flag to indicate whether to print status messages to the console. Defaults to TRUE. Set to FALSE to suppress messages about the current processing step and run silently
...	Additional arguments to override the default, prescribed settings
confirm	(Deprecated) Use interactive_preview instead
num_previews	(Deprecated) Use preview_n instead
detrend_data	(Deprecated) A flag to indicate whether to run the detrend step (set to FALSE by default). Detrending your pupil time series can have unintended consequences; we thus recommend that users understand the implications of detrending – in addition to whether detrending is appropriate for the research design and question(s) – before using this function
skip_detransient	(Deprecated) A flag to indicate whether to skip the detransient step (set to FALSE by default). In most cases, this should remain FALSE. For a more detailed description about likely edge cases that would prompt you to set this to TRUE, see the docs for detransient()

Details

First, this glassbox function provides a highly opinionated prescription of steps and starting parameters we believe any pupillometry researcher should use as their defaults when preprocessing pupillometry data.

Second, and not mutually exclusive from the first point, using this function should ideally reduce the probability of accidental mishaps when "reimplementing" the steps from the preprocessing pipeline

both within and across projects. We hope to streamline the process in such a way that you could collect a pupillometry dataset and within a few minutes assess the quality of those data while simultaneously running a full preprocessing pipeline in 1-ish line of code!

Third, glassbox provides an "interactive" framework where you can evaluate the consequences of the parameters within each step on your data in real time, facilitating a fairly easy-to-use workflow for parameter optimization on your particular dataset. This process essentially takes each of the opinionated steps and provides a pre-/post-plot of the time series data for each step so you can adjust parameters and re-run the pipeline until you are satisfied with the choices of your parameters and their consequences on your pupil time series data.

Value

Preprocessed pupil data contained within an object of class `eyeris`

See Also

`lifecycle::deprecate_warn()`

Examples

```
demo_data <- eyelink_asc_demo_dataset()

# (1) examples using the default prescribed parameters and pipeline recipe

## (a) run an automated pipeline with no real-time inspection of parameters
output <- eyeris::glassbox(demo_data)

start_time <- min(output$timeseries$block_1$time_secs)
end_time <- max(output$timeseries$block_1$time_secs)

# by default, verbose = TRUE. To suppress messages, set verbose = FALSE.
plot(
  output,
  steps = c(1, 5),
  preview_window = c(start_time, end_time),
  seed = 0
)

## (b) run a interactive workflow (with confirmation prompts after each step)

output <- eyeris::glassbox(demo_data, interactive_preview = TRUE, seed = 0)

# (2) examples of overriding the default parameters
output <- eyeris::glassbox(
  demo_data,
  interactive_preview = FALSE, # TRUE to visualize each step in real-time
  deblink = list(extend = 40),
  lpfilt = list(plot_freqz = TRUE) # overrides verbose parameter
)
```

```
# to suppress messages, set verbose = FALSE in plot():
plot(output, seed = 0, verbose = FALSE)

# (3) examples of disabling certain steps
output <- eyeris::glassbox(
  demo_data,
  detransient = FALSE,
  detrend = FALSE,
  zscore = FALSE
)

plot(output, seed = 0)
```

interpolate

*Interpolate missing pupil samples***Description**

Linear interpolation of time series data. The intended use of this method is for filling in missing pupil samples (NAs) in the time series. This method uses "na.approx()" function from the zoo package, which implements linear interpolation using the "approx()" function from the stats package. Currently, NAs at the beginning and the end of the data are replaced with values on either end, respectively, using the "rule = 2" argument in the approx() function.

Usage

```
interpolate(eyeris, verbose = TRUE, call_info = NULL)
```

Arguments

eyeris	An object of class eyeris derived from load_asc()
verbose	A flag to indicate whether to print detailed logging messages. Defaults to TRUE. Set to FALSE to suppress messages about the current processing step and run silently
call_info	A list of call information and parameters. If not provided, it will be generated from the function call

Details

This function is automatically called by glassbox() by default. Use glassbox(interpolate = FALSE) to disable this step as needed.

Users should prefer using glassbox() rather than invoking this function directly unless they have a specific reason to customize the pipeline manually.

Value

An eyeris object with a new column in timeseries: pupil_raw_{...}_interpolate

Note

This function is part of the `glassbox()` preprocessing pipeline and is not intended for direct use in most cases. Use `glassbox(interpolate = TRUE)`.

Advanced users may call it directly if needed.

See Also

`glassbox()` for the recommended way to run this step as part of the full `eyeris` `glassbox` preprocessing pipeline.

For a complete, end-to-end reference pipeline that demonstrates how all `eyeris` preprocessing functions are chained together in practice, see the "Building Blocks Under the Hood" section of the *Anatomy of an eyeris Object* vignette — `vignette("anatomy", package = "eyeris")` — as well as the *Complete Pupillometry Pipeline Walkthrough* vignette: `vignette("complete-pipeline", package = "eyeris")`.

Examples

```
demo_data <- eyelink_asc_demo_dataset()

demo_data |>
  # set to FALSE to skip (not recommended)
  eyeris::glassbox(interpolate = TRUE) |>
  plot(seed = 0)
```

load_asc

Load and parse SR Research EyeLink .asc files

Description

This function builds upon the `eyelinker::read.asc()` function to parse the messages and meta-data within the EyeLink .asc file. After loading and additional processing, this function returns an S3 `eyeris` class for use in all subsequent `eyeris` pipeline steps and functions.

Usage

```
load_asc(
  file,
  block = "auto",
  binocular_mode = c("average", "left", "right", "both"),
  verbose = TRUE
)
```

Arguments

file	An SR Research EyeLink .asc file generated by the official EyeLink edf2asc command
block	Optional block number specification. The following are valid options: • "auto" (default): Automatically handles multiple recording segments embedded within the same .asc file. We recommend using this default as this is likely the safer choice then assuming a single-block recording (unless you know what you're doing). • NULL: Omits block column. Suitable for single-block recordings. • Numeric value: Manually sets block number based on the value provided here.
binocular_mode	Optional binocular mode specification. The following are valid options: • "average" (default): Averages the left and right eye pupil sizes. • "left": Uses only the left eye pupil size. • "right": Uses only the right eye pupil size. • "both": Uses both the left and right eye pupil sizes independently.
verbose	Logical. Whether to print verbose output (default TRUE).

Details

This function is automatically called by `glassbox()` by default. If needed, customize the parameters for `load_asc` by providing a parameter list.

Users should prefer using `glassbox()` rather than invoking this function directly unless they have a specific reason to customize the pipeline manually.

Value

An object of S3 class `eyeris` with the following attributes:

1. file: Path to the original .asc file.
2. timeseries: Data frame of all raw time series data from the tracker.
3. events: Data frame of all event messages and their time stamps.
4. blinks: Data frame of all blink events.
5. info: Data frame of various metadata parsed from the file header.
6. latest: `eyeris` variable for tracking pipeline run history.

For binocular data with `binocular_mode = "both"`, returns a list containing:

1. left: An `eyeris` object for the left eye data.
2. right: An `eyeris` object for the right eye data.
3. original_file: Path to the original .asc file.

Note

This function is part of the `glassbox()` preprocessing pipeline and is not intended for direct use in most cases. Provide parameters via `load_asc = list(...)`.

Advanced users may call it directly if needed.

See Also

`eyelinker::read.asc()` which this function wraps.

`glassbox()` for the recommended way to run this step as part of the full `eyeris` `glassbox` preprocessing pipeline.

For a complete, end-to-end reference pipeline that demonstrates how all `eyeris` preprocessing functions are chained together in practice, see the "Building Blocks Under the Hood" section of the *Anatomy of an eyeris Object* vignette — `vignette("anatomy", package = "eyeris")` — as well as the *Complete Pupillometry Pipeline Walkthrough* vignette: `vignette("complete-pipeline", package = "eyeris")`.

Examples

```
demo_data <- eyelink_asc_demo_dataset()

demo_data |>
  eyeris::glassbox(load_asc = list(block = 1))

# Other useful parameter configurations
## (1) Basic usage (no block column specified)
demo_data |>
  eyeris::load_asc()

## (2) Manual specification of block number
demo_data |>
  eyeris::load_asc(block = 3)

## (3) Auto-detect multiple recording segments embedded within the same
## file (i.e., the default behavior)
demo_data |>
  eyeris::load_asc(block = "auto")

## (4) Omit block column
demo_data |>
  eyeris::load_asc(block = NULL)
```

Description

The intended use of this method is for smoothing, although by specifying `wp` and `ws` differently one can achieve highpass or bandpass filtering as well. However, only lowpass filtering should be done on pupillometry data.

Usage

```
lpfilt(
    eyeris,
    wp = 4,
    ws = 8,
    rp = 1,
    rs = 35,
    plot_freqz = FALSE,
    call_info = NULL
)
```

Arguments

<code>eyeris</code>	An object of class <code>eyeris</code> derived from <code>load_asc()</code>
<code>wp</code>	The end of passband frequency in Hz (desired lowpass cutoff). Defaults to 4
<code>ws</code>	The start of stopband frequency in Hz (required lowpass cutoff). Defaults to 8
<code>rp</code>	Required maximal ripple within passband in dB. Defaults to 1
<code>rs</code>	Required minimal attenuation within stopband in dB. Defaults to 35
<code>plot_freqz</code>	A flag to indicate whether to display the filter frequency response. Defaults to FALSE
<code>call_info</code>	A list of call information and parameters. If not provided, it will be generated from the function call. Defaults to NULL

Details

This function is automatically called by `glassbox()` by default. If needed, customize the parameters for `lpfilt` by providing a parameter list. Use `glassbox(lpfilt = FALSE)` to disable this step as needed.

Users should prefer using `glassbox()` rather than invoking this function directly unless they have a specific reason to customize the pipeline manually.

Value

An `eyeris` object with a new column in time series: `pupil_raw_{...}_lpfilt`

Note

This function is part of the `glassbox()` preprocessing pipeline and is not intended for direct use in most cases. Provide parameters via `lpfilt = list(...)`.

Advanced users may call it directly if needed.

See Also

`glassbox()` for the recommended way to run this step as part of the full `eyeris` `glassbox` preprocessing pipeline

For a complete, end-to-end reference pipeline that demonstrates how all `eyeris` preprocessing functions are chained together in practice, see the "Building Blocks Under the Hood" section of the *Anatomy of an `eyeris` Object* vignette — `vignette("anatomy", package = "eyeris")` — as well as the *Complete Pupillometry Pipeline Walkthrough* vignette: `vignette("complete-pipeline", package = "eyeris")`.

Examples

```
demo_data <- eyelink_asc_demo_dataset()

demo_data |>
  # set lpfilt to FALSE (instead of a list of params) to skip step
  eyeris::glassbox(lpfilt = list(plot_freqz = TRUE)) |>
  plot(seed = 0)
```

pipeline_handler

Build a generic operation (extension) for the `eyeris` pipeline

Description

`pipeline_handler` enables flexible integration of custom data processing functions into the `eyeris` pipeline. Under the hood, each preprocessing function in `eyeris` is a wrapper around a core operation that gets tracked, versioned, and stored using this `pipeline_handler` method. As such, custom pipeline steps must conform to the `eyeris` protocol for maximum compatibility with the downstream functions we provide.

Usage

```
pipeline_handler(eyeris, operation, new_suffix, ...)
```

Arguments

<code>eyeris</code>	An object of class <code>eyeris</code> containing time series data in a list of data frames (one per block), various metadata collected by the tracker, and <code>eyeris</code> specific pointers for tracking the preprocessing history for that specific instance of the <code>eyeris</code> object
<code>operation</code>	The name of the function to apply to the time series data. This custom function should accept a data frame <code>x</code> , a string <code>prev_op</code> (i.e., the name of the previous pupil column – which you DO NOT need to supply as a literal string as this is inferred from the latest pointer within the <code>eyeris</code> object), and any custom parameters you would like

new_suffix	A character string indicating the suffix you would like to be appended to the name of the previous operation's column, which will be used for the new column name in the updated preprocessed data frame(s)
...	Additional (optional) arguments passed to the operation method

Details

Following the `eyeris` protocol also ensures:

- all operations follow a predictable structure, and
- that new pupil data columns based on previous operations in the chain are able to be dynamically constructed within the core time series data frame.

Value

An updated `eyeris` object with the new column added to the `timeseries` data frame and the latest pointer updated to the name of the most recently added column plus all previous columns (ie, the history "trace" of preprocessing steps from start-to-present)

See Also

For more details, please check out the following vignettes:

- Anatomy of an `eyeris` Object

```
vignette("anatomy", package = "eyeris")
```

- Building Your Own Custom Pipeline Extensions

```
vignette("custom-extensions", package = "eyeris")
```

Examples

```
# first, define your custom data preprocessing function
winsorize_pupil <- function(x, prev_op, lower = 0.01, upper = 0.99) {
  vec <- x[[prev_op]]
  q <- quantile(vec, probs = c(lower, upper), na.rm = TRUE)
  vec[vec < q[1]] <- q[1]
  vec[vec > q[2]] <- q[2]
  vec
}

# second, construct your `pipeline_handler` method wrapper
winsorize <- function(eyeris, lower = 0.01, upper = 0.99, call_info = NULL) {
  # create call_info if not provided
  call_info <- if (is.null(call_info)) {
    list(
      call_stack = match.call(),
      parameters = list(lower = lower, upper = upper)
    )
  } else {
    call_info
  }
}
```

```

    }

    # handle binocular objects
    if (eyeris:::is_binocular_object(eyeris)) {
      # process left and right eyes independently
      left_result <- eyeris$left |>
        pipeline_handler(
          winsorize_pupil,
          "winsorize",
          lower = lower,
          upper = upper,
          call_info = call_info
        )

      right_result <- eyeris$right |>
        pipeline_handler(
          winsorize_pupil,
          "winsorize",
          lower = lower,
          upper = upper,
          call_info = call_info
        )

      # return combined structure
      list_out <- list(
        left = left_result,
        right = right_result,
        original_file = eyeris$original_file,
        raw_binocular_object = eyeris$raw_binocular_object
      )

      class(list_out) <- "eyeris"

      return(list_out)
    } else {
      # regular eyeris object, process normally
      eyeris |>
        pipeline_handler(
          winsorize_pupil,
          "winsorize",
          lower = lower,
          upper = upper,
          call_info = call_info
        )
    }
  }
}

# and voilà, you can now connect your custom extension
# directly into your custom `eyeris` pipeline definition!
custom_eye <- system.file("extdata", "memory.asc", package = "eyeris") |>
  eyeris::load_asc(block = "auto") |>
  eyeris::deblink(extend = 50) |>
  winsorize()

```

```
plot(custom_eye, seed = 1)
```

plot.eyeris

Plot pre-processed pupil data from eyeris

Description

S3 plotting method for objects of class `eyeris`. Plots a single-panel timeseries for a subset of the pupil time series at each preprocessing step. The intended use of this function is to provide a simple method for qualitatively assessing the consequences of the preprocessing recipe and parameters on the raw pupillary signal.

Usage

```
## S3 method for class 'eyeris'
plot(
  x,
  ...,
  steps = NULL,
  preview_n = NULL,
  preview_duration = NULL,
  preview_window = NULL,
  seed = NULL,
  block = 1,
  plot_distributions = FALSE,
  suppress_prompt = TRUE,
  verbose = TRUE,
  add_progressive_summary = FALSE,
  eye = c("left", "right", "both"),
  num_previews = deprecated()
)
```

Arguments

<code>x</code>	An object of class <code>eyeris</code> derived from <code>load_asc()</code>
<code>...</code>	Additional arguments to be passed to <code>plot</code>
<code>steps</code>	Which steps to plot; defaults to all (i.e., plot all steps). Otherwise, pass in a vector containing the index of the step(s) you want to plot, with index 1 being the original raw pupil time series
<code>preview_n</code>	Number of random example "epochs" to generate for previewing the effect of each preprocessing step on the pupil time series
<code>preview_duration</code>	Time in seconds of each randomly selected preview

preview_window	The start and stop raw timestamps used to subset the preprocessed data from each step of the eyeris workflow for visualization Defaults to NULL, meaning random epochs as defined by preview_n and preview_duration will be plotted. To override the random epochs, set preview_window here to a vector with relative start and stop times (in seconds), for example – c(5,6) – to indicate the raw data from 5-6 secs on data that were recorded at 1000 Hz). Note, the start/stop time values indicated here are in seconds because eyeris automatically computes the indices for the supplied range of seconds using the \$info\$sample.rate metadata in the eyeris S3 class object
seed	Random seed for current plotting session. Leave NULL to select preview_n number of random preview "epochs" (of preview_duration) each time. Otherwise, choose any seed-integer as you would normally select for <code>base::set.seed()</code> , and you will be able to continue re-plotting the same random example pupil epochs each time – which is helpful when adjusting parameters within and across eyeris workflow steps
block	For multi-block recordings, specifies which block to plot. Defaults to 1. When a single .asc data file contains multiple recording blocks, this parameter determines which block's time series to visualize. Must be a positive integer not exceeding the total number of blocks in the recording
plot_distributions	Logical flag to indicate whether to plot both diagnostic pupil time series <i>and</i> accompanying histograms of the pupil samples at each processing step. Defaults to FALSE
suppress_prompt	Logical flag to disable interactive confirmation prompts during plotting. Defaults to TRUE, which avoids hanging behavior in non-interactive or automated contexts (e.g., RMarkdown, scripts) Set to FALSE only when running inside <code>glassbox()</code> with <code>interactive_preview = TRUE</code> , where prompting after each step is desired, as well as in the generation of interactive HTML reports with bidsify
verbose	A logical flag to indicate whether to print status messages to the console. Defaults to TRUE. Set to FALSE to suppress messages about the current processing step and run silently
add_progressive_summary	Logical flag to indicate whether to add a progressive summary plot after plotting. Defaults to FALSE. Set to TRUE to enable the progressive summary plot (useful for interactive exploration). Set to FALSE to disable the progressive summary plot (useful in automated contexts like bidsify reports)
eye	For binocular data, specifies which eye to plot: "left", "right", or "both". Defaults to "left". For "both", currently plots left eye data (use eye="right" for right eye data)
num_previews	(Deprecated) Use preview_n instead

Value

No return value; iteratively plots a subset of the pupil time series from each preprocessing step run

Examples

```
# first, generate the preprocessed pupil data
my_eyeris_data <- system.file("extdata", "memory.asc", package = "eyeris") |>
  eyeris::load_asc() |>
  eyeris::deblink(extend = 50) |>
  eyeris::detransient() |>
  eyeris::interpolate() |>
  eyeris::lpfilt(plot_freqz = TRUE) |>
  eyeris::zscore()

# controlling the time series range (i.e., preview window) in your plots:

## example 1: using the default 10000 to 20000 ms time subset
plot(my_eyeris_data, seed = 0, add_progressive_summary = TRUE)

## example 2: using a custom time subset (i.e., 1 to 500 ms)
plot(
  my_eyeris_data,
  preview_window = c(0.01, 0.5),
  seed = 0,
  add_progressive_summary = TRUE
)

# controlling which block of data you would like to plot:

## example 1: plots first block (default)
plot(my_eyeris_data, seed = 0)

## example 2: plots a specific block
plot(my_eyeris_data, block = 1, seed = 0)

## example 3: plots a specific block along with a custom preview window
## (i.e., 1000 to 2000 ms)
plot(
  my_eyeris_data,
  block = 1,
  preview_window = c(1, 2),
  seed = 0
)
```

plot_binocular_correlation

Plot binocular correlation between left and right eye data

Description

Creates correlation plots showing the relationship between left and right eye measurements for pupil size, x-coordinates, and y-coordinates. This function is useful for validating binocular data quality and assessing the correlation between the two eyes.

Usage

```
plot_binocular_correlation(
  eyeris,
  block = 1,
  variables = c("pupil", "x", "y"),
  main = "",
  col_palette = "viridis",
  sample_rate = NULL,
  verbose = TRUE
)
```

Arguments

eyeris	An object of class eyeris derived from <code>load_asc()</code> with binocular data, or a list containing left and right eyeris objects (from <code>binocular_mode = "both"</code>)
block	Block number to plot (default: 1)
variables	Variables to plot correlations for. Defaults to <code>c("pupil", "x", "y")</code> for pupil size, x-coordinates, and y-coordinates
main	Title for the overall plot (default: "Binocular Correlation")
col_palette	Color palette for the plots (default: "viridis")
sample_rate	Sample rate in Hz (optional, for time-based sampling)
verbose	Logical flag to indicate whether to print status messages (default: TRUE)

Value

No return value; creates correlation plots

Examples

```
# For binocular data loaded with binocular_mode = "both"
binocular_data <- load_asc(eyelink_asc_binocular_demo_dataset(), binocular_mode = "both")
plot_binocular_correlation(binocular_data)

# For binocular data loaded with binocular_mode = "average"
# (correlation plot will show original left vs right before averaging)
avg_data <- load_asc(eyelink_asc_binocular_demo_dataset(), binocular_mode = "average")
plot_binocular_correlation(avg_data$raw_binocular_object)
```

plot_gaze_heatmap	Create gaze heatmap of eye coordinates
-------------------	--

Description

Creates a heatmap showing the distribution of eye_x and eye_y coordinates across the entire screen area. The heatmap shows where the participant looked most frequently during the recording period.

Usage

```
plot_gaze_heatmap(
  eyeris,
  block = 1,
  screen_width = NULL,
  screen_height = NULL,
  n_bins = 50,
  col_palette = "viridis",
  main = "Gaze Heatmap",
  xlab = "Screen X (pixels)",
  ylab = "Screen Y (pixels)",
  sample_rate = NULL,
  eye_suffix = NULL
)
```

Arguments

eyeris	An object of class eyeris derived from load_asc()
block	Block number to plot (default: 1)
screen_width	Screen width in pixels from eyeris\$info\$screen.x
screen_height	Screen height in pixels from eyeris\$info\$screen.y
n_bins	Number of bins for the heatmap grid (default: 50)
col_palette	Color palette for the heatmap (default: "viridis")
main	Title for the plot (default: "Fixation Heatmap")
xlab	X-axis label (default: "Screen X (pixels)")
ylab	Y-axis label (default: "Screen Y (pixels)")
sample_rate	Sample rate in Hz (optional)
eye_suffix	Eye suffix for binocular data (default: NULL)

Value

No return value; creates a heatmap plot

Examples

```
demo_data <- eyelink_asc_demo_dataset()
eyeris_preproc <- glassbox(demo_data)
plot_gaze_heatmap(eyeris = eyeris_preproc, block = 1)
```

process_chunked_query *Process large database query in chunks*

Description

Handles really large databases by processing queries in reasonably sized chunks to avoid memory issues. Data can be written to CSV or Parquet files as it's processed.

Usage

```
process_chunked_query(
  con,
  query,
  chunk_size = 1e+06,
  output_file = NULL,
  process_chunk = NULL,
  verbose = TRUE
)
```

Arguments

con	Database connection
query	SQL query string to execute
chunk_size	Number of rows to fetch per chunk (default: 1000000)
output_file	Optional output file path for writing chunks. If provided, chunks will be appended to this file. File format determined by extension (.csv or .parquet)
process_chunk	Optional function to process each chunk. Function should accept a data.frame and return logical indicating success. If not provided and output_file is specified, chunks are written to file.
verbose	Whether to print progress messages (default: TRUE)

Value

List containing summary information about the chunked processing

Examples

```
## Not run:
# These examples require an existing eyeris database

con <- eyeris_db_connect("/path/to/bids", "my-project")

# Process large query and write to CSV
process_chunked_query(
  con,
  "SELECT * FROM large_table WHERE condition = 'something'",
  chunk_size = 50000,
  output_file = "large_export.csv"
)

# Process large query with custom chunk processing
process_chunked_query(
  con,
  "SELECT * FROM large_table",
  chunk_size = 25000,
  process_chunk = function(chunk) {
    # Custom processing here
    processed_data <- some_analysis(chunk)
    return(TRUE)
  }
)

eyeris_db_disconnect(con)

## End(Not run)
```

read_eyeris_parquet	<i>Read parquet files back into R</i>
---------------------	---------------------------------------

Description

Convenience function to read the parquet files created by `eyeris_db_to_parquet` back into a single data frame or list of data frames by data type.

Usage

```
read_eyeris_parquet(
  parquet_dir,
  db_name = NULL,
  data_type = NULL,
  return_list = FALSE,
  pattern = "*.parquet",
  verbose = TRUE
)
```

Arguments

parquet_dir	Directory containing the parquet files, or path to database-specific folder
db_name	Optional database name to read from (if parquet_dir contains multiple database folders)
data_type	Optional data type to read (if NULL, reads all data types)
return_list	Whether to return a list by data type (TRUE) or combined data frame (FALSE, default)
pattern	Pattern to match parquet files (default: "*.parquet")
verbose	Whether to print progress messages (default: TRUE)

Value

Combined data frame from all parquet files, or list of data frames by data type

Examples

```
# Minimal self-contained example that avoids database creation
if (requireNamespace("arrow", quietly = TRUE)) {
  # create a temporary folder structure: parquet/<db_name>
  base_dir <- file.path(tempdir(), "derivatives", "parquet")
  db_name <- "example-db"
  dir.create(file.path(base_dir, db_name), recursive = TRUE, showWarnings = FALSE)

  # write two small parquet parts for a single data type
  part1 <- data.frame(time = 1:5, value = 1:5)
  part2 <- data.frame(time = 6:10, value = 6:10)
  arrow::write_parquet(
    part1,
    file.path(
      base_dir, db_name, paste0(db_name, "_timeseries_part-01-of-02.parquet")
    )
  )
  arrow::write_parquet(
    part2,
    file.path(
      base_dir, db_name, paste0(db_name, "_timeseries_part-02-of-02.parquet")
    )
  )

  # read them back as combined data frame
  data <- read_eyeris_parquet(base_dir, db_name = db_name)

  # read as list by data type
  data_by_type <- read_eyeris_parquet(base_dir, db_name = db_name, return_list = TRUE)

  # read specific data type only
  timeseries_data <- read_eyeris_parquet(base_dir, db_name = db_name, data_type = "timeseries")
}
```

summarize_confounds	<i>Extract confounding variables calculated separately for each pupil data file</i>
---------------------	---

Description

Calculates various confounding variables for pupil data, including blink statistics, gaze position metrics, and pupil size characteristics. These confounds are calculated separately for each preprocessing step, recording block, and epoch time series in the `eyeris` object.

Usage

```
summarize_confounds(eyeris)
```

Arguments

`eyeris` An object of class `eyeris` derived from `load_asc()`

Value

An `eyeris` object with a new nested list of data frames: `$confounds`. The confounds are organized hierarchically by block and preprocessing step. Each step contains metrics such as:

- Missing data (`n_missing` and `prop_missing`)
- Blink rate and duration statistics
- Gaze position (x,y) mean and standard deviation
- Pupil size mean, standard deviation, and range

Missing data is reported as both a count (`n_missing`) and a proportion (`prop_missing`, 0 to 1; multiply by 100 for a percentage) of NA samples. It is computed at two levels so you can choose the granularity appropriate to your design:

- **Block level:** `confounds$unepoched_timeseries[[block]][[step]]` reports `prop_missing` across the entire recording block.
- **Epoch/trial level:** `confounds$epoched_timeseries[[epoch]][[block]]` reports `prop_missing` for each epoch event (e.g., per trial).

`eyeris` intentionally does not enforce a fixed missing-data exclusion cutoff. Instead, `prop_missing` is exposed so you can define your own exclusion thresholds at whichever level (trial, epoch, or block) is appropriate for your study.

Examples

```
# load demo dataset
demo_data <- eyelink_asc_demo_dataset()

# calculate confounds for all blocks and preprocessing steps
confounds <- demo_data |>
```

```

eyeris::glassbox() |>
eyeris::epoch(
  events = "PROBE_{type}_{trial}",
  limits = c(-1, 1), # grab 1 second prior to and 1 second post event
  label = "prePostProbe" # custom epoch label name
) |>
eyeris::summarize_confounds()

# access confounds for entire time series for a specific block and step
confounds$confounds$unepoched_timeseries

# access confounds for a specific epoched time series
# for a specific block and step
confounds$confounds$epoched_timeseries
confounds$confounds$epoched_epoch_wide

```

zscore	<i>Z-score pupil time series data</i>
--------	---------------------------------------

Description

The intended use of this method is to scale the arbitrary units of the pupil size time series to have a mean of 0 and a standard deviation of 1. This is accomplished by mean centering the data points and then dividing them by their standard deviation (i.e., z-scoring the data, similar to `base::scale()`). Opting to z-score your pupil data helps with trial-level and between-subjects analyses where arbitrary units of pupil size recorded by the tracker do not scale across participants, and therefore make analyses that depend on data from more than one participant difficult to interpret.

Usage

```
zscore(eyeris, call_info = NULL)
```

Arguments

eyeris	An object of class <code>eyeris</code> derived from <code>load_asc()</code>
call_info	A list of call information and parameters. If not provided, it will be generated from the function call

Details

This function is automatically called by `glassbox()` by default. Use `glassbox(zscore = FALSE)` to disable this step as needed.

Users should prefer using `glassbox()` rather than invoking this function directly unless they have a specific reason to customize the pipeline manually.

In general, it is common to z-score pupil data within any given participant, and furthermore, z-score that participant's data as a function of block number (for tasks/experiments where participants complete more than one block of trials) to account for potential time-on-task effects across task/experiment blocks.

As such, if you use the `eyeris` package as intended, you should NOT need to specify any groups for the participant/block-level situations described above. This is because `eyeris` is designed to preprocess a single block of pupil data for a single participant, one at a time. Therefore, when you later merge all of the preprocessed data from `eyeris`, each individual, preprocessed block of data for each participant will have already been independently scaled from the others.

Additionally, if you intend to compare mean z-scored pupil size across task conditions, such as that for memory successes vs. memory failures, then do NOT set your behavioral outcome (i.e., success/failure) variable as a grouping variable within your analysis. If you do, you will consequently obtain a mean pupil size of 0 and standard deviation of 1 within each group (since the scaled pupil size would be calculated on the time series from each outcome variable group, separately). Instead, you should compute the z-score on the entire pupil time series (before epoching the data), and then split and take the mean of the z-scored time series as a function of condition variable.

Value

An `eyeris` object with a new column in time series: `pupil_raw_{...}_z`

Note

This function is part of the `glassbox()` preprocessing pipeline and is not intended for direct use in most cases. Use `glassbox(zscore = TRUE)`.

Advanced users may call it directly if needed.

See Also

[glassbox\(\)](#) for the recommended way to run this step as part of the full `eyeris` `glassbox` preprocessing pipeline

For a complete, end-to-end reference pipeline that demonstrates how all `eyeris` preprocessing functions are chained together in practice, see the "Building Blocks Under the Hood" section of the *Anatomy of an `eyeris` Object* vignette — `vignette("anatomy", package = "eyeris")` — as well as the *Complete Pupillometry Pipeline Walkthrough* vignette: `vignette("complete-pipeline", package = "eyeris")`.

Examples

```
demo_data <- eyelink_asc_demo_dataset()

demo_data |>
  eyeris::glassbox(zscore = TRUE) |> # set to FALSE to skip (not recommended)
  plot(seed = 0)
```
